COMPANY DEEP-DIVE

Director of Digital Operations & AI Enablement at Skan.AI Believes Agentic AI Will Shape the Future of Process Intelligence Platforms

DATE PUBLISHED
14 Sep 2026

INTERVIEW DATE
16 Jun 2026

EXPERT PERSPECTIVE
Competitor

ANALYST PERSPECTIVE
Investor-Led (Buy-Side)

PRIMARY COMPANY
MIMICA AUTOMATION

SMART SUMMARY

Summary

The interview covers the technology, competitive landscape, and customer use cases for enterprise process intelligence platforms, with a focus on how these solutions are deployed, differentiated, and evolving in the market.

EXPERT BACKGROUND

- Director of Digital Operations & AI Enablement at an enterprise process intelligence software company, responsible for AI solutions, digital operations, and implementing transformation strategies for customers and internal teams.

EXPERT SENTIMENT

- Believes the future of process intelligence will be dominated by platforms that can enable agentic AI and integrate digital and human workforces.
- Views the biggest competitive threat as coming from foundational AI providers (e.g., OpenAI, Anthropic) that could make specialized process intelligence platforms obsolete.
- Expects some process intelligence companies to be acquired by larger tech or automation firms, while others may remain independent if they achieve sufficient scale.

TAKEAWAYS

- Process intelligence platforms differentiate by the granularity and breadth of data they capture; visual observation combined with backend integration is a key advantage.
- Traditional log-based approaches (e.g., Celonis) face challenges with integration, data completeness, and adaptability to changing application ecosystems.
- The market includes competitors like Mimica (speed-focused), Soroco (workflow focus), and UiPath (automation and process intelligence), with implementation partners such as Wipro, TCS, Infosys, and Accenture playing key roles.
- Customer usage can be both project-based and recurring, with continuous monitoring favored in large, complex operations (e.g., BFSI, manufacturing, healthcare, private equity).
- The largest opportunities are in North America and Europe, especially with large enterprises, but mid-market companies also benefit, primarily through automation to reduce cost to serve.

Expert Bio

Director – Digital Operations & AI Enablement at Skan.AI, a competitor of Mimic. The expert can speak to their leadership in digital operations and AI enablement at Skan AI, a company operating in the process automation domain, providing insights into the market and competitive landscape relevant to Mimica Automation. Director – Digital Operations & AI Enablement at Skan.AI. The expert is responsible for building and leading an AI Center of Excellence while driving digital operations and process transformation across the organization.

©2026, AlphaSense, Inc. All Rights Reserved. AlphaSense is a service mark of AlphaSense, Inc. All other trademarks mentioned belong to their respective owners.

They also focus on enabling adoption and leveraging data intelligence to improve operational performance and decision-making. Former Analytics Engagement Leader || AI Strategy, Transformation and Value Realization at Koch. The expert works with Koch's investment companies to help them transform operations in the supply chain, sales, marketing and more using AI and data. The expert is a customer of Amazon Web Services and Microsoft Azure. In the connectors segment supply chain, the expert deployed a production schedule optimization for the CFO, creating $5-12M annually per plant, among many other optimizations across different segments in the company. The expert is also the Secretary and a Member of the Board Of Directors at Facing Forward to End Homelessness. The expert drives case management through digital transformation. Former Strategic Partner and Financial Advisor at Mondeaux Dam Lodge LLC, leaving in August 2024. The expert created the business plan, go-to-market strategy, and financial statements to win a federal contract with the National Parks Service. The expert also optimized cash-flow processes, helped consolidate debt, helped optimize supplier and payables strategy and introduced New Point-of-Sale (POS) system.

Interview Transcript

Client 00:00:00
Thanks for speaking with me about the AI automation space. Maybe just very quickly, what's your role in the organization, and what do you do there?

Expert 00:00:08
I really run AI solutions and digital operations.

Client 00:00:13
Cool. What does that mean, digital operations?

Expert 00:00:17
Okay. We have a product that helps our customers gather intelligence about their own process. We have teams of people who help our customers deploy this product in their ecosystem to start looking at the data and the insights that our product is deploying. Our consultants help them think through what is a good transformation strategy. Really, the goal of a product like this is to transform your operations because you're looking at the process, you're understanding details that you never could see before, and now you want to see how to change the process.

Throughout all of this, there are people involved in setting up the product, making sure the product is working well, making sure that it is capturing the right data. We have to then analyze the data to make sure we have the right insights. We have to pull the insights together into a comprehensive transformation strategy. All of this is operations.

Through all of this, my goal is to see how we can digitize different steps throughout these operations, streamline, basically optimize the process. Some of my work is, in fact, dogfooding. The recommendations that we provide to our customers on how they can improve their processes, I'm implementing some of those internally for our teams to become more efficient.

Client 00:01:41
Got it. Maybe if you could just help me understand Skan AI on what the business is? Also, another one we've heard about is called Mimica. If that's doing the same thing or slightly different, can you just help me understand these businesses?

Expert 00:01:56
Yeah. Let me take a slightly broader view and stop me at any point if you want me to go narrower.

Client 00:02:04
Just to flag, we are not throughout the space. We generally are high-level explainers on the space.

Expert 00:02:10
Great. You understand the space. The way any of these typical companies, whether it be Mimica, Skan, etc., is they're trying to establish a relationship with the entire enterprise because we're an enterprise product. We really want to have multiple relationships. We want to solve business problems that are extremely valuable for that organization. Everyone tries to get to the problems that are most important for this customer.

Typically, you would look at competing in spaces, which are operationally extremely complex or intensive. That way, we are all similar. The actual product might be different because the underlying technology that extracts the process details is different. The technology that Skan

©2026, AlphaSense, Inc. All Rights Reserved. AlphaSense is a service mark of AlphaSense, Inc. All other trademarks mentioned belong to their respective owners.

makes is slightly different from what Mimica makes, etc. The advantage that Skan brings to the table, because I'm more familiar with Skan, of course, is our data is more granular. Our data is also more wider reading.

Client 00:03:14

Can you explain the technology and how they're different? Maybe explain Skan's technology to start with.

Expert 00:03:22

This is where I will get into some details. The basic goal is to be able to observe the work that is done by different users. Historically, if you look at technologies that have been big players in this space, that would be someone like Celonis. The way Celonis has historically operated is they would connect to the backend logs of your different applications that are in use and get the usage telemetry from those applications. Depending on how much detail is available in which application, they're able to get granular.

The biggest use case for that was, historically, SAP. SAP, as an ERP, was used across most, especially analog operations. Celonis was able to tap into the logs of SAP and really understand where people are spending time, which screens are people spending time on, and as a result of that, map out where time and effort is being spent throughout the process, all the way from this is the customer order because the ERP is all-encompassing. From the customer order all the way to supply planning, to logistics, to fulfillment of that order, everything is captured in the ERP.

Now, there are multiple challenges in this process because of which customers don't necessarily get everything that they want. One of the things is it requires a lot of integration. These products have to integrate, have to connect to multiple applications, which are being used by the end users. They have to understand what's the underlying operating language, connect with those back-end systems and extract their logs, and then interpret those logs.

Now, as those applications evolve, those logs change. Their understanding of these logs has to be constantly updated. If a new application enters the ecosystem or if an application is removed, now suddenly, they have to play the catch-up game of, "I have to hook up to this new application. I need to get logs." There are a lot of applications which might not even let you connect to the back end and capture their logs.

There was a clear gap in the market because the existing products were not really solving the entire need. The data either wouldn't be granular enough, number one. two, It will not be all-encompassing. It would not capture data from all my applications in the process. As a result, it never gives me a complete picture. The third thing is time. It takes a lot of time to get to the data.

Now, all the competitors of Celonis since have tried to solve different parts of that problem in different ways. Mimica does well in speed. Skan does well in the other two areas, for sure. Skan data is a lot more granular than anything you can find because the way we approach it is not using logs, but we actually visually observe all the things that the end user is doing, in addition to capturing information from the back end. It's a lot more sophisticated IP, which is able to use multiple techniques to extract process. As a result, we are more granular. As a result, we are also more all-encompassing as a technology in the sense that we can observe lot more applications.

You can imagine maybe 99% of your usage application space can be observed through Skan. Very few exceptions. That allows us to differentiate ourselves because we can really get you very granular and a complete view of your process. As you can see, different companies, as they come up with their newer versions, they're trying to improve their capabilities in one of the other areas. As we are coming up with newer versions, our goal is to be faster. When I say faster, the goal is not just to get faster data. The goal is to really cut down the time to insights and action.

The only way any enterprise product like ours can show value to our customer is if the customer is able to implement or take action based on some insight, and as a result, capture value. We want to track all the way up until there. The faster we are able to allow our customers to take action and measure those, the better we are able to tell value narratives, and hence, we become stickier.

Client 00:07:51

Got it. Maybe a few questions. Taking a step back to what you had mentioned on Celonis, what are the limitations of the systems logs? To your point, is it the fact that you have to connect with all the different applications, or can you just do it by connecting with SAP or the ERP?

Expert 00:08:09

Sorry. If I understood your question, are you asking what is the underlying challenge with just having to connect with just one ERP?

Client 00:08:19

No. What's the underlying challenge with using the systems logs approach of a Celonis?

©2026, AlphaSense, Inc. All Rights Reserved. AlphaSense is a service mark of AlphaSense, Inc. All other trademarks mentioned belong to their respective owners.

Expert 00:08:25

There are a few issues. Number one, the information that is captured in the logs is driven by what that particular application decides to capture. Let's say you, as an enterprise, are using multiple applications. Sales team is using Salesforce. You have a bunch of other people using Etsy, and you have the accounting team using QuickBooks. Now, the logs captured by each of these technologies are different. First, you have to integrate with each of the existing logs, and let's understand what does connecting to a log mean. It means that a log file is capturing certain pieces of information, and you're going to try and read that.

The application which is pushing out that log at any point can decide that it needs to capture or display less or more information. SAP, Salesforce, they can at any point change what gets written into their logs because they're not writing their logs for us, they're writing their logs for themselves. You're, first of all, immediately dependent on an application that you have no control on in the ecosystem.

Secondly, any changes that happen to either that application in the ecosystem or other applications. Let's say, today, Celonis works in the current setup. You decided that you're going to change your CRM from Salesforce to something else, or you decided to introduce a new application called LeasePLUS to manage leases or whatever.

Now, suddenly you have to do a whole bunch of new wiring, which is a lot of work. Every time you need to connect to a log to read information from it, every time the log changes or you get a new application or you have a change in the process, you have to go and change things, which means your process intelligence system is not going to be robust or dynamic enough. It will be a hard-wired slow system. That's the challenge.

There are a lot of applications which will actively prevent you from reading their logs because of security. In those cases, you have zero data getting captured from those applications. That makes it harder. If you can imagine, especially a lot of your applications which have VPN-based securities, require additional layers of data transfers, which makes it easy for you to get stuck behind a firewall if you work with logs.

Client 00:10:50

This is super helpful. Again, just to make sure I understand the limitations, let's say, you have Celonis in an organization. You're able to connect all these different applications. There are no changes. How accurate or how easy is it to then interpret all of those logs and do the task mining or build out the process maps? Is it that straightforward and very accurate, or is it still opaque?

Expert 00:11:17

See, the problem is this. It takes a long time to set up in a system like this where you have to connect with logs. Now, if you do take the effort to connect all of it, the expectation is it will probably be more accurate. You are correct. However, by the time you finish connecting everything, what you were connecting for does not remain the same.

By the time you finish building all the connections to your logs, the world has changed. You no longer need the same information that you were seeking when you started that exercise because the idea of data being stagnant does not exist. Your data will always change. The idea that you can have a stagnant system and it be accurate is going to work for a very small time because data changes quickly. Even if you wire everything up, it will be very accurate probably for some time, but you'll start seeing drifts.

Client 00:12:15

Got it. That's clear on the system logs approach. Now, this approach that you've described with Skan AI, where they visually observe everything, did you say they also capture information by integrating with the technology? Are they also doing the systems logs, or maybe I missed that part?

Expert 00:12:34

Let me put it this way. Let's say that you're reading an HTML page. You can visually look at what the HTML page is saying, but if you're technology, you can also just inspect source. You can right-click on the page as a human, click on Inspect Source, and it'll show you all the code in the backend that is making your HTML come alive. As human beings, that's how we operate. When we are analyzing something, you're going to look at the "metadata", which is what we did when we inspected the HTML page. You look at what is happening on the page visually.

When we build our solutions, we try to do both, which means that you suddenly now are looking at every activity done by a human being, but you're looking at it from multiple lenses. You're trying to get as much information about that process as possible. You're going to visually try to understand what they're doing. You're additionally going to try and see if you can understand what they're doing by looking at the back-end information. If I'm using technology, I can process this information differently, and I can extract insights differently.

Let's say that if I'm going to analyze. This is a good example. Email communication is going to be probably a very important part of any enterprise process you take. Outlook, how do you connect with Outlook? You can build a connector that connects with the back end and captures information, but you also want to see how are people using Outlook. Where is time being spent? Are people spending most of their

©2026, AlphaSense, Inc. All Rights Reserved. AlphaSense is a service mark of AlphaSense, Inc. All other trademarks mentioned belong to their respective owners.

time just navigating through inbox? Maybe one of the automation solutions that I need to do is prioritize and triage incoming emails.

If you want to solve that problem, you have to understand what is happening. You cannot truly understand what's happening if you don't do both, visually see what's happening and understand the content of what is being touched. We build connectors that not only extract the back-end information wherever available, but we also are visually seeing what the person is doing. Where are they clicking? Why are they doing this? Why are they scrolling? Are they copying and pasting something? Now you have a complete picture of digital operations, and then you can put together a strategy on how to transform it.

Client 00:15:06

That makes sense. Mimica, do they not also have the visual view of what the person is. They're also able to visually observe what's going on?

Expert 00:15:15

Yeah. Because we are competitors, I wouldn't have too much insight into the details of exactly what they're doing. One thing we can see is that most products out there will have technology to work in the back end in some way, in the sense that they'll be working with the logs, or they'll be connecting with the application in some way to extract some data that the application already is willing to share with you easily. Every product has some of those. Not every product has complementary additional skills like visually looking at some pieces, but they have their own differentiation in some way.

For example, Celonis, it works with back-end logs, but it is very familiar with SAP. It has so much subject matter expertise around SAP that most large enterprises that work on SAP will probably benefit from working with Celonis for those processes where SAP does a good job for them. I don't have the specifics of exactly what differentiates each product, but I can tell you where we typically have seen strengths.

With Mimica, one of the strengths that we've seen is they're typically faster. My guess is that they have some better data processing capabilities in the back end somewhere. I don't know if it is native to their product or they just have really smart people who are able to do that in the back end. I don't know that answer, but I know where their strengths are.

Client 00:16:44

That's helpful. Maybe one more question on just the vendor landscape. Who are the other main competitors you see Skan AI comes up against in this space?

Expert 00:16:56

Soroco and UiPath are the other two that I've heard.

Client 00:17:00

UiPath, are they not more RPA, or they also do their own process intelligence?

Expert 00:17:05

It's a little bit of both. At the end of the day, what is the point of process intelligence? Intelligence by itself is useless unless you're able to take action. Typically, you will have two kinds of actions. You're going to automate stuff and streamline things, or you're going to improve your processes. There's a third thing. You're going to change your teams. People, process, and technology, those are the three areas that you're going to try and impact. All of these solutions will impact those three areas. UiPath is a little more focused on automation because they bring automation solutions. They're focused on surfacing automation opportunities as a part of process intelligence, but they still do process intelligence.

Client 00:17:59

Got it. Skan AI and UiPath, for example, are they partners where you guys will do the process intelligence and then partner on to that?

Expert 00:18:08

They're not partners, but our customers sometimes have both of us in the ecosystem. They might be already using UiPath to automate. They might use us to surface more automation opportunities and have, say, someone like Wipro or TCS have other implementation partners who are working with, say, Skan products to identify automation opportunities, and then working with the UiPath product to actually automate those.

©2026, AlphaSense, Inc. All Rights Reserved. AlphaSense is a service mark of AlphaSense, Inc. All other trademarks mentioned belong to their respective owners.

Client 00:18:35
Got it. The implementation partners you mentioned, what were they called?

Expert 00:18:40
Implementation partners, some examples I was giving was of companies like Wipro or Tata Consultancy Services, Infosys, Accenture, they're all implementing, Ernst & Young. Those would be implementation partners who might be either working with us or working with the customer. Let's say a big bank. Take any big bank. Wells Fargo might be working with Ernst & Young. Ernst & Young might use Skan to identify the automation opportunities and then use UiPath to implement automations for Wells Fargo.

Client 00:19:16
Got it. The other one you mentioned, was this Soroco, you said?

Expert 00:19:21
Soroco.

Client 00:19:24
Makes sense. They say they're more AI for human workflows. Where would you see them fitting in?

Expert 00:19:33
They're all doing process intelligence. At the end of the day, you can look at it from different views. You can look at it purely from an ERP standpoint like Celonis, or you can look at it from a workflow standpoint like Soroco. For us, I think the goal is to become your digital twin of operations. That's really the goal because that's what everyone's trying to do, create a digital twin so that I can actually see what's happening with my operations.

This is where we are also now getting into a world of agents. All of these have to now start thinking about how to manage your analog and digital workforces. That's really the goal of all of these. It's process intelligence, but process intelligence with the goal of influencing people, process, technology.

Client 00:20:22
That makes total sense. Maybe another question, what does customer usage look like today? On one hand, this can feel very much project-based, bringing a Skan or a Mimica or a Soroco in on a case-by-case basis. How do customers use Skan today? What are the main use cases that you see from customers? How do they expand, if ever, or is it more one-off or recurring, if it's recurring?

Expert 00:20:48
There's always case for recurring revenue. The goal is this, transformation is never a one-time thing. What that means is, let's say, you're a big company. Let us just continue the example that we're talking through, Wells Fargo. Wells Fargo now wants to, say, become AI forward. What does that mean? Let's say every time a customer walks into the bank, they should submit an application. Within 24 hours, they should hear the status automatically, with very little touch. Sorry, I got lost in the question. Do you mind repeating?

Client 00:21:27
My question is, is this project-based? Talking process mining, is this project-based, or is this software that your customers pay for on a recurring basis? What happens when you run out of processes to mine, customer mine?

Expert 00:21:44
The goal is continuous monitoring because your transformation is not static. What does that mean? You have, say, a team of 10,000 people who are processing claims out in India for Wells Fargo and Bangladesh. Let's say you have an offshore team. You have very little control on how much time they spend, what they're working on because you can't talk to any of those employees. It's an offshore model. You can talk to one manager, perhaps. Now, suddenly, you can see what 10,000 people are doing because you have Skan deployed on their machines.

What that does next is, first, you identify what changes or what transformation opportunities exist. You realize that, number one, I have out of 10,000 people, these 10 people are not working at all, so I'm going to let them go. These 30 people, I'm going to put them on a performance improvement plan. Clearly, they need certain skills which my data is telling me they lack. I'm going to make some process changes. Now, my team is organized into A, B, C, but I will reorganize it. That, I believe, will give me optimization. I'm also going to automate pieces.

©2026, AlphaSense, Inc. All Rights Reserved. AlphaSense is a service mark of AlphaSense, Inc. All other trademarks mentioned belong to their respective owners.

For example, I'm going to integrate Outlook and CRM and Salesforce so that people don't have to switch from an email to Salesforce all the time. They don't have to copy content from an email, put it in Salesforce. All of that, I'm automating now. To answer your question, if you are implementing this, how do you measure the changes, whether they're taking impact or not?

Client 00:23:29

No. The point is, if you are doing screen recordings of someone's software, that's not continuous? That will be for two weeks, and then you take it out.

Expert 00:23:40

No, it is continuous. What you want to do is you are continuously adding new things. Now, there are some use cases which fit for a continuous monitoring. Let's say you have a BPO of 10,000 people, and you're processing claims. The operations managers want to see a cockpit where in the morning they want to come in and see, "Okay, how are my cases being processed? What is the health of my operating model? Are cases being stuck somewhere? Do I have bottlenecks anywhere? I need to go fix those. Do I need to go respond to some customers because they are stuck behind the process?" This is an actual use case of what we do today.

There are operations managers who are continuously monitoring their processes because it is a large, complex machinery of a lot of people doing a lot of things, and that's how it keeps running. Anytime it gets stuck, money is lost. This is a continuous monitoring exercise. Not every use case will fit that. Some use cases will fit just my, "Hey, I observe for two, three weeks, then go make some changes. Observe again for two, three weeks, and then go make changes." For some, that is the best model. For some use cases, there's a very clear fit for continuous monitoring because I'm constantly pushing updates, especially if it's a complex and large-scale process.

Client 00:25:08

Got it. Could you maybe explain the technology at Skan? If it's continuous monitoring and you're doing screen recordings, does that mean you have 100 people in the Philippines every day looking at those recordings and making sense of the processes from that? It feels quite intensive from an operations perspective to do all of this.

Expert 00:25:29

Which is why you have technology doing a lot of the heavy lift.

Client 00:25:34

Okay. Can you explain the technology?

Expert 00:25:37

You have images of work being done. From images, you have to extract data, that's really the metadata. That metadata is collected continuously and harnessed, and then that metadata is analyzed to determine what is the actual process flow. How are cases stitched together? How is a case progressing from stage one to stage two to stage three? All of that intelligence happens, and then we surface recommendations from there.

It could be things like, "Hey, your processing time is, right now, 30 minutes per case." A lot of that time is being spent switching between these three applications, and here are the reasons they're switching. They're copying this information, pasting it here because Outlook is not integrated. They are trying to look up this customer information because their status is only available in this other website.

The technology is going to analyze all of this data and then say, "Hey, here are my recommendations for automation opportunities." What are people doing through all of this? People are making sure that this is connected to the right things. We are observing the right things. We are pulling the right data. At the end of the day, once the automation opportunities or the process change recommendations are surfaced, as much as technology has done the heavy lift of surfacing those, the humans have to work with the business leaders to understand how to make this a plan.

An idea doesn't become a plan without conversation. That's what the consultants are doing, and then the plan has to be implemented, measured, reported on. All of that our teams have to do, which is consulting work, which every product team has services attached. This is where your product is more powerful if it is doing more of the heavy lift instead of the people doing the heavy lift. Anywhere data is involved, we have the product do the heavy lifting.

©2026, AlphaSense, Inc. All Rights Reserved. AlphaSense is a service mark of AlphaSense, Inc. All other trademarks mentioned belong to their respective owners.

Client 00:27:44

Got it. In terms of an output, a typical output for Skan, what does it look? Does it look like a service delivery model at the end to walk the enterprise through the findings and automation to suggest recommendations? Does it just look like you sharing process maps and then an integration or a consultancy partner then an implementation partner does the rest? What does it look like?

Expert 00:28:08

Yeah. This is very much up to the customer. Different customer organizations are at different levels of maturity. Even within a same organization, different teams are at different levels of maturity. Some teams and some companies are very good at taking just our product and driving action from there. They will say, "Just deploy the product. Help us understand how it works, and help us set up a center of excellence. We will run it from here." They're very good at doing that because they have those skills. They have built those teams to really sustain that.

A lot of customers are not adept at doing that. We have to help either set up those teams for them, or we have to be those teams for them, and they'll pay for it. There is always a combination of product and service, especially because a large enterprise, very complex product like process intelligence, you need people to enable adoption. Otherwise, people just won't get it. In addition to complexities of being a process intelligence product, our product is more complex because it is more sophisticated.

Like I said, it looks at more granular data. It looks at all applications, and it surfaces a lot of insights automatically out the door, which means that the product has to do a lot of heavy lifting, which means it is complex, which means that people have to be involved to enable users. The goal is to get to action, and we're very clear with the customer on that transformation strategy.

Do you have the skills and the capabilities to drive action and transformation once you start seeing insights? Do you need us to help with that? Based on that, we'll align on what services package they really need. We don't want to necessarily make money on services. We want to make money on licenses like any product company.

Client 00:30:06

That makes sense. Could you give me a sense of where you see this market evolving? UiPath and Automation Anywhere, they've both made acquisitions in this process intelligence space and the task mining space. Do you think, actually, companies like Skan, Mimica, there's a world where, in 10 years' time, they're still independent, or do you think they get acquired by some of the RPA guys that focus on automation, or even implementation partners?

Expert 00:30:33

Yeah. I think that there will be some that will get acquired, for sure. There will be some that cannot get acquired. Eventually, what will happen is these products will become fairly big that they will replace a lot of human capital. There will be some products which an implementation partner cannot just buy up and use as their own. They will have to only partner up. Salesforce is an example, in my opinion. I know it's not in the same field, but I took something outside the field on purpose to make a point.

Salesforce is very massive that by itself, as a CRM, it works. At the right time, it could have been acquired by an implementation partner and say, "Hey, we will implement CRMs for you." Likewise, I think some might get acquired, but there will be some that will stay independent. Some might get acquired by actual product companies. I also imagine Microsoft, Dell, and Apple, at some point, might acquire one of these process intelligence companies and have them be part of their enterprise offering.

Client 00:31:44

Okay. Maybe another way of asking this question is, how does Skan compete against UiPath when they have their own process intelligence tool?

Expert 00:31:52

Yeah. Let me ask you this. Aree you trying to figure out how would a company in this field remain competitively differentiated over time?

Client 00:32:01

Yes. I'm trying to know who wins in this market.

Expert 00:32:07

Got it. To your question of who wins, right now, the companies are going towards agentic. Agentic, agentic. What does that mean? Let me unpack that for a minute. Companies that do not work on building a capability of agentic AI will die. There is no other way around it. A company in process intelligence, that is not going to able directly build agents or enable building of agents in some way, in the sense that, "Hey, I'm creating data using which you can generate your agents, or you can build agents through me, which UiPath does already."

If you don't do that, it'll be hard for you to compete because lot of companies are going to come and say, "I not only show you where the opportunities for intelligence is, but I'll actually build agents for you." UiPath does that. Skan also does that. Skan also builds agents for our customers. We have products that does that. More and more of those will come out. Eventually, it'll become commoditized. Building an agent will not be a differentiation, but will be a basic out-of-the-box capability.

You take any enterprise software now. You take ClickUp. You take Freshdesk. You take HubSpot, Salesforce, any CRM, any ops management. Any program management tool you take has an AI component in there. You can build your agents within that platform. Building agents will become commoditized. What's the point of building agents? It's because, eventually, what we are doing is moving work from physical human capital to digital workforces. If your process intelligence is not able to give you a sense of how your physical and digital workforces work together, you are not going to survive in the market. That is where we are heading.

Client 00:34:14

Maybe not for Skan, but for the competitors that you see in the market like a UiPath, for example. I would imagine they can bundle this together and have a cheaper price. We've heard Mimica's pricing is quite competitive, so maybe just on competition's pricing, how does it work? What have you heard?

Expert 00:34:33

A lot of the price-based competition conversation happens with our sales team, not necessarily the conversations that I sit in. I'm trying to see if I have any insight into this. As much as I've heard of a few things, there is nothing stood out that says, "We do really well against a competitor because of price," or "A competitor does really well against us for price." I have not heard any of that.

Client 00:35:01

Makes sense. Last question, are there any other vendors in this space that may be slightly earlier or newer vendors that you've heard a lot of positive things about? Any other names we should be aware of? We spoke about UiPath, Soroco, Mimica.

Expert 00:35:18

Yeah. Our biggest competition is none of these. Biggest competition is Anthropic and OpenAI. You know why? Once Claude figures out how to do this themselves, they don't need us. You don't need an enterprise product if every machine has AI already. It's connected to most of the systems. It is embedded in your operating system like Microsoft Copilot. Eventually, one of these people are going to figure out how to capture process telemetry, and then all your process intelligence platforms will become obsolete. That's the biggest threat.

Client 00:35:58

That's a really good point. Completely agree with that point. I don't know if it's something they'll do, but I completely agree that is the biggest risk here. If they don't do this, are there any other companies that you're hearing about?

Expert 00:36:12

Nothing more than the list that we've discussed. I think the list of names that we've discussed come up in different scenarios. As you can imagine, market is not uniform, like big players, small players, let's say, industries. Clearly, some of these do well in some places over another. Sometimes it just depends on where your sales team has better relationships. Otherwise, these are typically the names that come up. I haven't seen anything outside. Once in a while, I'll hear OpenAI or Anthropic.

Client 00:36:48

Where does Skan AI, in particular, do well just from a use case perspective? Also, maybe even from a geo or a customer ICP perspective, where is the focus of the organization so I understand where you guys fit in.

Expert 00:37:02

North America is where your big customers are, North America and Europe. The biggest opportunity that we've seen is really in complex and large operations. Hundreds of people, thousands of people working on things, especially offshore operations and so on. That scale, typically, we are seeing for banking, insurance. Your BFSI segment, your banking, financial services, insurance segment, typically, has a lot of people processing transactions in different places. That is your largest segment, followed by manufacturing.

Manufacturing also has a lot of people doing a lot of things globally. Manufacturing is a big segment. Everything is changing. Suddenly, now AI has disrupted two big fields, has disrupted software engineering and has disrupted legal. Suddenly, software engineering, all your software engineering companies want to re-optimize processes because they have to rethink how to work with digital employees.

Private equity. Every private equity is a portfolio of a bunch of companies. How do you do process intelligence across? Working with private equity is a good use case, which everyone has known, but now really that becomes a strategy for certain fields, so anywhere where you have large complex operations. Healthcare also is another good example. Usually, are a good fit. Right now, in terms of complex operations and money, it's North America and Europe, which are your biggest markets. As much as you have markets in Asia too, everything is going through disruption right now. North America and Europe are your major markets.

Client 00:38:57

Would you then say that you're not that relevant, or you don't see yourself as relevant for mid-market companies?

Expert 00:39:03

We are, but what they will need from us is different. If you look at a mid-market company, they are not looking at complexity of scale, but they're looking at cost to serve. They do work with us. We work with mid-market companies. Their main focus is it is same people process technology. As you can imagine, if I have 10,000 people, if I make one small change in process, I have a lot more to gain. If I have 40 people working on a process, making a process change will not give me a lot of lift.

Likewise, I can let go of three people who are not working well and replace them with better people, but that won't really give me the biggest lift. The same thing, if I'm doing that for 10,000 people, I let go of 3% and replace them with better performance, that is a big lift. For your small, medium companies, really, your biggest benefit comes in automation because that truly lifts their cost to serve. Let's say you're looking at a collections process. A mid-market company who is giving, say, $100,000 worth of loans, but they're giving 10,000 of those loans out, and they're managing that with just 40 people.

For that, if I improve automation, the value for that company is so much more than anything else. Really, depending on the company you are, the action that you can take which is most valuable for you is different, whereas in really big companies, they can immediately make changes with people and process. If they have to make technology changes, it takes time because somebody has to build it, test it, implement it, get consensus, and so on. It is valuable, but the paths to value is different.

Client 00:40:55

This has been really helpful. Thank you so much. Have a good day.
